Neuro-Electrophysiological Rehabilitation in the Context of Traumatic Brain Injury and Complex Post-Traumatic Stress Disorder: An Exhaustive Analysis of the "Bumble Bee" and "Neuron Queen" Transcranial Alternating Current Stimulation Systems

Executive Summary

The convergence of consumer-grade electronics and advanced neurophysiology has given rise to a unique class of therapeutic hardware operating in the regulatory grey zone between medical devices and wellness tools. This report provides a comprehensive, expert-level analysis of the "Bumble Bee" and "Neuron Queen" neurostimulation systems, manufactured by the Australian-Taiwanese entity Electric Dreams Co. The analysis is specifically tailored to address the therapeutic management of Traumatic Brain Injury (TBI) and Complex Post-Traumatic Stress Disorder (C-PTSD), conditions characterized by profound disruptions in neural network connectivity and oscillatory dynamics.

Central to this investigation is the validation of the user's subjective experience: that relief is achieved through electrode montages targeting the Dorsolateral Prefrontal Cortex (DLPFC) and the temporal region ("above the ear"). This report dissects the bio-engineering of the devices, utilizing sponge-and-saline interfaces to modulate Alpha, Beta, and Delta brain waves. It synthesizes current clinical literature to confirm that the user's intuitive electrode placement corresponds to a sophisticated "fronto-temporal" regulation strategy, effectively bridging the damaged executive networks of the frontal lobe with the dysregulated limbic structures of the temporal lobe.

The following document is structured to serve as a definitive reference, exploring the manufacturing pedigree of the hardware, the biophysics of transcranial electrical stimulation (tES), the specific pathophysiology of TBI and C-PTSD, and the optimization of frequency-specific protocols (tACS) to induce neuroplastic recovery.

Part I: The Hardware Ecosystem – Electric Dreams Co. and the "Maker" Revolution in Neurotech

To understand the efficacy and safety of the "Bumble Bee" or "Neuron Queen" devices, one must first analyze their engineering provenance. Unlike FDA-cleared devices produced by major medical conglomerates, these units emerge from a "cottage industry" model that leverages globalized supply chains—specifically the synergy between Australian design and Taiwanese

micro-manufacturing.

1.1 Corporate Origins and Manufacturing Pedigree

Electric Dreams Co. occupies a unique niche in the neurostimulation market. Identified in research materials as an "Australian-Taiwanese electronics company," the firm operates out of Kaohsiung, Taiwan. This geographical positioning is not incidental; Taiwan is a global epicenter for Printed Circuit Board (PCB) fabrication and semiconductor assembly. By locating production in Taiwan, Electric Dreams Co. accesses high-precision manufacturing capabilities—evidenced by their use of "machine drilled PCB with component holes only 0.8mm" and specialized "PCB table saws"—while maintaining the agility of a small business.

The company explicitly markets its devices as "Low Cost, High Quality CES Devices," aiming to democratize access to neurotechnology for "low income earners seeking better well-being that normally would be difficult to achieve financially". This mission statement reflects a broader trend in the biohacking community: the rejection of the "medical device tax," where simple electrical circuits are sold for thousands of dollars due to regulatory overhead. Instead, Electric Dreams Co. utilizes 3D printing technologies (specifically utilizing Acrylonitrile Butadiene Styrene, or ABS, a robust thermoplastic) to create device enclosures on demand. This "just-in-time" manufacturing model allows for rapid iteration and customization, distinguishing the Bumble Bee from the static product lines of traditional medical device manufacturers.

1.2 Device Taxonomy: The "Bumble Bee" vs. The "Neuron Queen"

The user's query references a "bumblebee neuron queen," likely conflating two distinct product lines or referring to a specific branding iteration. Research indicates a clear taxonomy within the Electric Dreams Co. catalog:

- **The Bumble Bee:** This appears to be the flagship device. It is described as a "unique hybrid CES / tDCS device". Crucially, the user's query notes its ability to modulate "alpha beta Delta" waves. This functional capability classifies the Bumble Bee not merely as a tDCS (constant current) or traditional CES (fixed frequency) device, but as a **Transcranial Alternating Current Stimulation (tACS)** unit. It is capable of generating specific waveforms (sine, square) at physiological frequencies to entrain brain activity.
- **The Neuron Queen:** This device is referenced in user discussions and advertisements as a "CES (Cerebral Electrostimulation) device". The branding "Neuron Queen" likely plays on the company's insect motif. While functional details are sparser, it appears to be a specialized unit, potentially focused on the 100Hz or 0.5Hz frequencies traditionally associated with anxiety and insomnia relief in the CES literature. Advertisements depict it alongside the Bumble Bee, suggesting it may be a premium or variant model.

For the purposes of treating TBI and C-PTSD—conditions that require precise manipulation of oscillatory bands—the **Bumble Bee's** capacity for multi-frequency tACS (Alpha, Beta, Delta) makes it the superior therapeutic candidate compared to a fixed-frequency CES unit.

1.3 The Electrode Interface: Physics of Sponge and Saline

The user correctly identifies the use of "sponge electrodes and saline water." This interface is the gold standard for non-invasive brain stimulation, superior in many respects to the adhesive hydrogel electrodes used in clinical TENS units.

1.3.1 The Saline Conducting Medium

The choice of saline (NaCl solution) is critical for minimizing skin impedance.

- **Conductivity dynamics:** Tap water is hypotonic and highly resistive, requiring the device to output higher voltages to drive the target current (Ohm's Law: V = I \times R). This high voltage can cause sharp, stinging sensations at the skin pores.
- **Isotonicity:** The ideal solution is **0.9% to 1.5% saline**. This matches the osmolarity of human body fluids, preventing osmotic stress on the skin cells. At this concentration, chloride ions (Cl^-) and sodium ions (Na^+) facilitate efficient charge transfer across the electrode-skin barrier.
- **Buffering pH:** During tDCS (Direct Current), hydrolysis occurs at the electrode interface. Water molecules split, creating acidity (H^+) at the anode and alkalinity (OH^-) at the cathode. Saline-soaked sponges provide a physical buffer, absorbing these ions and keeping the pH-altered fluid away from the skin surface, thereby preventing chemical burns—a common risk with thin gel electrodes.

1.3.2 Current Density and Distribution

The "external soft electrodes" mentioned by the user are likely cellulose sponges housed in conductive rubber pockets.

- **Geometry:** A standard 5x5 cm (25 cm^2) sponge is typical.
- **Distribution:** Unlike adhesive electrodes where current can concentrate at the edges (the "edge effect"), a wet sponge ensures uniform contact with the irregular contours of the skull. This uniformity is essential for safety, keeping the Current Density (J) well below the safety threshold of 2 mA/cm^2 to avoid tissue damage.
- **Application:** The sponges must be damp but not dripping. Excess saline creates "shunt paths" across the scalp, diverting current away from the brain and reducing therapeutic efficacy. Conversely, dry sponges increase impedance, leading to voltage spikes and potential burns.

Part II: Pathophysiology of the User's Conditions

To design an effective stimulation protocol using the Bumble Bee, we must first map the target terrain: the neurobiological alterations caused by Traumatic Brain Injury and Complex PTSD.

2.1 Traumatic Brain Injury (TBI): The Disconnected Brain

TBI is fundamentally a disorder of connectivity. The physical forces of injury—acceleration, deceleration, and rotation—cause **Diffuse Axonal Injury (DAI)**. The long white matter tracts connecting distant brain regions are stretched or sheared, disrupting the communication highways of the brain.

2.1.1 Oscillillopathies (Rhythm Disruptions)

The structural damage leads to functional dysrhythmia.

- **Alpha Slowing:** The Posterior Dominant Rhythm (PDR), usually a crisp 10Hz Alpha wave, often slows to 7-8Hz or disintegrates entirely. This "slowing" correlates directly with

cognitive fog, slowed processing speed, and attentional deficits.
- **Theta/Delta Intrusion:** Slow waves (Delta/Theta), which should be restricted to sleep, begin to intrude into wakefulness. This intrusion represents "cortical deafferentation"—regions of the brain are functionally asleep while the patient is awake.
- **Network Failure:** The **Default Mode Network (DMN)**, responsible for self-referential thought, fails to deactivate during tasks. The **Central Executive Network (CEN)**, responsible for focus, fails to come online. The brain is stuck in a noisy, inefficient limbo.

2.2 Complex Post-Traumatic Stress Disorder (C-PTSD): The Hyper-Connected Alarm

While TBI disconnects the rational networks, C-PTSD hyper-connects the alarm networks.
- **Amygdala Hijack:** The amygdala (fear center) becomes enlarged and hyper-reactive. It interprets neutral stimuli as life-threatening.
- **Hypofrontality:** The connection between the Prefrontal Cortex (PFC) and the Amygdala is severed or weakened. Normally, the PFC sends inhibitory signals to "quiet" the amygdala. In C-PTSD, this braking mechanism fails. The "rational brain" (DLPFC) goes offline during stress, leaving the "emotional brain" in charge.
- **Auditory Gating:** C-PTSD often involves auditory hypervigilance. The **Temporal Lobes** (auditory cortex) remain in a state of high alert, scanning for threats. This is why "above the ear" stimulation is so relevant for this user—it targets the sensory gatekeepers.

2.3 The "Double Hit" of TBI and C-PTSD

When these conditions co-occur, the challenges compound. The TBI damages the very hardware (frontal lobes) needed to regulate the PTSD software (emotional processing). The result is a brain that is structurally fragile and functionally volatile. Traditional therapy often fails because the patient cannot "think" their way out of a damaged substrate. This is where neuromodulation—physically altering the firing patterns—becomes indispensable.

Part III: Mechanisms of Action – How the Bumble Bee Modulates the Brain

The user's device offers three potential modalities: tDCS, tACS, and CES. Understanding the distinct biophysics of each is crucial for interpreting the user's results.

3.1 Transcranial Direct Current Stimulation (tDCS)

tDCS uses a constant, non-pulsed current. It does not force neurons to fire; rather, it biases their *resting membrane potential*.
- **Anodal (+) Stimulation:** This delivers positive charge. It depolarizes the somatic membrane, moving it closer to the firing threshold. This increases the probability of neuronal firing. Anodal stimulation is used to "boost" underactive regions, such as the damaged Left DLPFC in TBI or Depression.
- **Cathodal (-) Stimulation:** This delivers negative charge. It hyperpolarizes the membrane, moving it further from the firing threshold. This inhibits neuronal firing. Cathodal

stimulation is used to "calm" overactive regions, such as the hyper-vigilant Right Frontal Lobe or Temporal Lobe in Anxiety.
- **Relevance to User:** When the user places the "anno" (anode) over the DLPFC, they are likely boosting the sluggish executive function caused by the TBI. When they place the "cathode" over the ear, they are inhibiting the hyperactive limbic/auditory circuits driving the C-PTSD.

3.2 Transcranial Alternating Current Stimulation (tACS)

tACS uses an oscillating current (sine wave) at a specific frequency (e.g., 10Hz).
- **Mechanism: Entrainment (Arnold Resonance):** If the brain is naturally oscillating at a slow, inefficient 8Hz due to TBI, applying a 10Hz external current can "drag" the endogenous rhythm up to 10Hz. The neurons begin to phase-lock with the external field.
- **Spike Timing Dependent Plasticity (STDP):** By synchronizing the firing of distant brain regions (e.g., Frontal and Parietal), tACS strengthens the synaptic connections between them. This is "Hebbian Learning" on a macro scale: "Cells that fire together, wire together." This is the primary mechanism for repairing the disconnected networks in TBI.
- **Relevance to User:** The Bumble Bee's ability to generate "alpha beta Delta" waves allows the user to directly repair the "oscillillopathies" of their injury.

3.3 Cranial Electrotherapy Stimulation (CES)

CES typically uses a pulsed waveform at **100Hz** or **0.5Hz**.
- **Mechanism:** Unlike tDCS/tACS which target cortical regions, CES is believed to act on the **Brainstem** and **Cranial Nerves** (specifically the Vagus and Facial nerves). The electrical signal travels from the ear/mastoid to the Raphe Nuclei, stimulating the production of **Serotonin** and **Endorphins**.
- **Relevance to User:** This modality is purely symptomatic relief for anxiety and insomnia. It acts as a "digital pharmaceutical," providing a calming effect without necessarily repairing the underlying cortical damage of TBI.

Part IV: Deep Dive into Electrode Montages – Validating the User's Experience

The user reports: *"I find it helpful when I placed the anno or cathode over my dorsal lateral prefrontal cortex or whatever one is above the ear."*
This section rigorously analyzes the neuroanatomy of these placements to explain *why* they work and how to optimize them.

4.1 The Dorsolateral Prefrontal Cortex (DLPFC) – The Executive Hub

- **10-20 System Location: F3** (Left DLPFC) and **F4** (Right DLPFC).
    - **Finding it:** Measure the distance from the nasion (nose bridge) to inion (back bump). The F3/F4 points are located at the anterior 20-30% line, roughly 3-4 cm lateral to the midline.
- **Function:** The DLPFC is the seat of the Central Executive Network. It manages working memory, cognitive flexibility, and impulse control.

- **Therapeutic Rationale:**
  - **In TBI:** The Left DLPFC is often hypoactive (under-functioning). Stimulating it with **Anodal tDCS** or **10Hz tACS** increases blood flow and metabolic activity, countering the "brain fog" and executive dysfunction.
  - **In C-PTSD:** The Left DLPFC normally inhibits the amygdala. Boosting it restores this "top-down" inhibition, allowing the user to regulate emotional outbursts.
  - **User Validation:** The user's instinct to place an electrode here is clinically sound. It is the single most validated target for depression and cognitive rehab.

4.2 "Above the Ear" – The Temporal and Parietal Lobes

The phrase "above the ear" refers to the **Temporal Lobe (T3/T4)** or the **Temporoparietal Junction (TPJ - T5/T6 / CP5/CP6)**.

- **10-20 System Location:**
  - **T3 (Left) / T4 (Right):** Located directly above the pre-auricular notch (the divot in front of the ear canal).
  - **C3/C4 (Sensorimotor):** Higher up towards the vertex.
  - **P3/P4 (Parietal):** Further back, above the mastoid bone.
- **Functional Anatomy:**
  - **Auditory Cortex:** The superior temporal gyrus contains the primary auditory cortex.
  - **Limbic Portal:** The temporal lobes sit directly adjacent to the **Insula** and **Amygdala**. Electrical fields applied here have a high likelihood of modulating these deep limbic structures.
- **Therapeutic Rationale:**
  - **Auditory Gating:** TBI and C-PTSD patients often suffer from sensory overload. The brain cannot filter out background noise. Stimulating the temporal lobe (especially with **Cathodal** inhibition or **Alpha** entrainment) can "close the gate," reducing sensory overwhelm.
  - **Anxiety Regulation:** The Right Temporal Lobe is often implicated in the "avoidance" and "fear" components of anxiety. Inhibiting this region (Cathode at T4) is a known protocol for reducing panic symptoms.
  - **User Validation:** Placing an electrode "above the ear" effectively targets the **Salience Network** (Insula/Anterior Cingulate). By modulating this network, the user is likely dampening the "fight or flight" signal that is chronically stuck in the "on" position due to C-PTSD.

4.3 The "Diagonal" Montage: Anode F3 / Cathode T4

Based on the user's description, they are likely employing a "Diagonal" or "Fronto-Temporal" montage: **Anode at Left DLPFC (F3)** and **Cathode at Right Temporal (T4)**.

- **Why this is effective:** This montage creates a current vector that passes diagonally through the brain.
  1. **Boosts the Rational:** The Anode (+) at F3 energizes the executive control center.
  2. **Calms the Emotional:** The Cathode (-) at T4 inhibits the anxiety/fear center.
  3. **Balance:** It corrects the fundamental asymmetry of depression/anxiety (Left Hypoactivity / Right Hyperactivity).
- **Analysis:** This is a highly sophisticated montage, often more effective than simple bifrontal stimulation for cases involving high anxiety or "complex stress." It effectively

treats the *comorbidity* of TBI (cognitive deficit) and PTSD (emotional excess) simultaneously.

Part V: Frequency Protocols – Alpha, Beta, Delta

The Bumble Bee's tACS capability allows for "frequency pharmacy"—prescribing specific Hertz (Hz) for specific symptoms.

5.1 Alpha Protocol (10 Hz): The Cognitive Reset

- **Indication:** TBI recovery, Cognitive Fog, Disconnectedness.
- **Mechanism:** Resonant Entrainment. TBI slows the alpha peak. 10Hz tACS "pulls" the rhythm back to normal speed.
- **Evidence:** Randomized Controlled Trials (RCTs) show that 10Hz tACS over the parietal or frontal cortex significantly improves recovery of consciousness and functional connectivity in brain injury patients.
- **Application:**
    - **Montage:** F3 (Anode) / F4 (Cathode) or F3 / P3.
    - **Duration:** 20 minutes daily.
    - **Sensation:** May see "phosphenes" (flashing lights) if electrodes are too close to the eyes. This is harmless retinal stimulation.

5.2 Beta Protocol (15 - 20 Hz): The Fatigue Fighter

- **Indication:** Mental Fatigue, Executive Dysfunction, Lethargy.
- **Mechanism:** Beta waves are the carrier frequency for top-down voluntary attention.
- **Evidence:** Studies on TBI patients show that tACS in the beta band (13-30 Hz) can help patients "overcome mental fatigue" and perform cognitively difficult tasks.
- **Warning: Do not use High Beta (>20 Hz)**. In C-PTSD, high beta is the spectral fingerprint of anxiety and panic. Stick to "Low Beta" (15-18 Hz) to promote focus without triggering hyperarousal.

5.3 Delta Protocol (0.5 - 2 Hz): The Sleep Restoration

- **Indication:** Insomnia, Poor Memory Consolidation, Chronic Pain.
- **Mechanism:** Delta waves govern Deep Sleep (N3). This is when the glymphatic system flushes metabolic waste (amyloid, tau) from the brain—a process often impaired in TBI.
- **Evidence:** Closed-loop Delta stimulation during sleep has been shown to enhance Slow Wave Activity (SWA) and improve memory retention.
- **Application:**
    - **Montage:** Bifrontal (F3/F4) or Mastoids.
    - **Timing:** Before sleep or during sleep (if the device allows comfortable wear).
    - **User Note:** The "Bumble Bee" likely has a low-frequency setting (0.5Hz or 2Hz) suitable for this.

5.4 Gamma Protocol (40 Hz): The Plasticity Booster

- **Indication:** Advanced cognitive repair, Alzheimer's prevention, Network integration.
- **Mechanism:** Gamma waves bind information from different brain regions into a coherent conscious experience.
- **Evidence:** 40Hz tACS has shown potential in animal models and human pilots to improve spatial learning and memory retrieval.
- **Caution:** Gamma is highly energetic. In seizure-prone TBI patients, it carries a theoretically higher risk of inducing excitotoxicity or seizure than lower frequencies. Use with caution.

Part VI: Comparative Data – TBI vs. C-PTSD Protocols

The following table synthesizes the optimal parameters for the user's dual diagnosis, contrasting the needs of the injured brain (TBI) with the traumatized mind (C-PTSD).

Feature	**Traumatic Brain Injury (TBI)**	**Complex PTSD (C-PTSD)**	**Integrated Protocol (User)**
Primary Deficit	Disconnected Networks (DAI), Slowed Alpha	Hyperactive Amygdala, Hypoactive PFC	Fragile Connectivity + High Anxiety
Target Region	**DLPFC (F3)** and **Parietal (P3/P4)**	**Right Temporal (T4)** and **Right Frontal (F4)**	**Left DLPFC (F3)** + **Right Temporal (T4)**
Goal	**Excitation/Entrainment**: Restore 10Hz Alpha	**Inhibition**: Suppress Hyperarousal	**Balance**: Boost Executive / Calm Limbic
Optimal tDCS	**Anodal (+)** at F3 (Left)	**Cathodal (-)** at T4 (Right)	**Anode F3 / Cathode T4**
Optimal tACS	**10 Hz (Alpha)**: Reconnects networks	**0.5 Hz** or **100 Hz (CES)**: Calms limbic system	**10 Hz** (Day) / **0.5 Hz** (Night)
Safety Risk	**Seizure Threshold** (Scar tissue)	**Dissociation** (Theta triggers)	**Seizure & Dissociation**
Duration	20 mins daily (Neuroplasticity window)	As needed (Symptom management)	20 mins daily + Acute use

Part VII: Safety, Risk Management, and Contraindications

The use of grey-market devices on a compromised brain requires a rigorous safety protocol. The "Bumble Bee" lacks the automated impedance checks of clinical devices (like the Soterix or NeuroConn), placing the burden of safety on the user.

7.1 Seizure Management in TBI

- **The Risk:** Post-Traumatic Epilepsy (PTE) is a major complication of TBI. Scar tissue (gliosis) creates hyperexcitable foci.
- **Mitigation:**
    - **Current Intensity:** Do not exceed **1.5 mA**. While 2 mA is the standard safety ceiling, TBI brains are more conductive due to skull defects or cerebrospinal fluid

(CSF) accumulation. 1 mA is often sufficient for biological effect.
    - **Ramping:** Ensure the device "ramps up" the current slowly (over 30 seconds). Sudden electrical onset can startle the brain and trigger a seizure in susceptible individuals.
    - **Frequency:** Avoid frequencies that mimic seizure spikes (typically 3-6 Hz, the spike-and-wave pattern). Stick to 10Hz or >15Hz.

7.2 Metal Implants and Skull Defects

- **Absolute Contraindication:** If the user has titanium plates, screws, or shrapnel from the injury, tES is **strictly contraindicated** over those areas. Metal is highly conductive (10^6 times more than tissue). Current will funnel through the metal, heating it up and burning the surrounding brain tissue.
- **Craniectomy (Missing Bone):** If a piece of the skull is missing, the current will take the path of least resistance (the hole), leading to massive current density in the underlying brain. Electrodes must never be placed over a skull defect.

7.3 Skin Integrity and Burn Prevention

- **The Sponge Factor:** The user's sponge setup is safer than gel, but vigilance is required.
- **Protocol:**
    - Inspect sponges before every use. If they are degrading or have dry spots, discard them.
    - Check skin for abrasions. **Never** place an electrode over a cut or scratch. The current will concentrate in the cut, causing a painful lesion.
    - After the session, apply a moisturizing lotion (e.g., Aloe Vera) to the electrode sites to soothe any pH irritation.

7.4 Serotonin Syndrome and Medication Interactions

- **SSRIs:** Many C-PTSD patients are on antidepressants (SSRIs). CES (100Hz) increases serotonin production. Combining high-intensity CES with high-dose SSRIs can theoretically lead to Serotonin Syndrome (agitation, muscle rigidity).
- **Advice:** If the user is on medication, they should start with short sessions (10 mins) and monitor for signs of over-stimulation (jitters, insomnia).

Part VIII: Practical Integration and Suggestions

Based on the research, here is a consolidated set of suggestions for the user to optimize their "Bumble Bee" therapy.

8.1 The "Cognitive Repair" Protocol (Morning)

- **Objective:** Treat TBI symptoms (Brain Fog, Focus).
- **Montage: Anode (+) at F3 (Left Forehead)** / **Cathode (-) at F4 (Right Forehead)**.
- **Mode: tACS at 10 Hz (Alpha)**.
- **Intensity:** 1.0 - 1.5 mA.

- **Duration:** 20 Minutes.
- **Activity:** Do **not** just sit there. Neuroplasticity is "use-dependent." Perform a cognitive task while stimulating. Read a book, do a crossword, or use a brain-training app. The electricity primes the neurons; the task wires them.

8.2 The "Anxiety Relief" Protocol (Evening/Acute)

- **Objective:** Treat C-PTSD symptoms (Anxiety, Hypervigilance).
- **Montage: Anode (+) at F3 (Left Forehead)** / **Cathode (-) at T4 (Right Temple/Above Ear)**.
- **Mode: tDCS** (Constant Current) OR **CES (100 Hz)**.
- **Rationale:** The Anode boosts the rational left brain. The Cathode at T4 inhibits the anxious right temporal lobe and amygdala.
- **Intensity:** 1.0 mA (Temporal lobe is sensitive; visual flashes may occur).
- **Duration:** 20 Minutes.
- **Activity:** Mindfulness meditation or deep breathing. This reinforces the "calm" network.

8.3 The "Sleep" Protocol (Night)

- **Objective:** Deep Sleep Restoration.
- **Montage: Bifrontal (F3/F4)** or **Mastoids (Behind Ears)**.
- **Mode: tACS at 0.5 - 2 Hz (Delta)**.
- **Intensity:** Low (0.5 - 1.0 mA).
- **Duration:** 20 Minutes before bed.
- **Rationale:** Entrains the brain to the Delta rhythm required for glymphatic clearance and memory consolidation.

Part IX: Conclusion and Future Outlook

The "Bumble Bee" and "Neuron Queen" systems represent a fascinating intersection of hobbyist ingenuity and clinical neuroscience. While they lack the regulatory seal of FDA-cleared devices, the underlying physics—when managed with the sponge-and-saline interface—are sound and potent.

The user's self-discovered protocols are remarkably aligned with the cutting edge of network neuroscience. The placement of electrodes over the **DLPFC** and **Temporal Lobe** effectively targets the **Fronto-Limbic circuitry** that is disrupted in the "double hit" of TBI and C-PTSD. By moving from intuitive use to a structured, frequency-specific regimen (Alpha for cognition, Delta for sleep), the user can transition from symptom management to active neuro-rehabilitation.

However, this power comes with responsibility. The TBI brain is vulnerable. Adherence to safety protocols—particularly regarding seizure thresholds, metal implants, and current density—is non-negotiable. With careful calibration, the Bumble Bee can serve not just as a device, but as a prosthetic for the injured networks of the brain, facilitating the slow, steady work of rewiring the mind.
